On certain Lagrangian subvarieties  
in minimal resolution of Kleinian singularities

- 1) Kleinian singularities
- 2) Anti-Poisson involution & their fixed loci
- 3) Preimage of fixed loci under minimal resolution

## Overview:

minimal resolution

$$\begin{array}{c} \widetilde{X} \\ \cup \\ \pi^{-1}(X^\theta) \end{array}$$

$$\xrightarrow{\pi}$$

Kleinian singularity

$$\begin{array}{c} X \\ \cup \\ X^\theta \end{array}$$

$\theta$  anti-Poisson involution

(singular) Lagrangian subvariety.

Goal: Describe  $X^\theta$  and  $\pi^{-1}(X^\theta)$  as schemes.  $\left\{ \begin{array}{l} \text{irreducible component} \\ \text{intersection pattern} \\ \text{reduced or not (multiplicity)} \end{array} \right.$

Motivation: Classification of irreducible  $HC(\mathfrak{g}, K)$ -mod

•  $G$  simple algebraic group;  $\mathfrak{g}$   $\mathcal{N}$ .

$\sigma: \mathfrak{g} \rightarrow \mathfrak{g}$ , Lie algebra involution  $\leadsto \mathfrak{g} = \mathfrak{k} \oplus \mathfrak{p}$ . K, corresponding alg group

A  $HC(\mathfrak{g}, K)$ -module is a f.g.  $U(\mathfrak{g})$ -mod,  $M$ , s.t.  $K \curvearrowright M$  locally finitely & integrates to  $K \curvearrowright M$ .

associated variety  $AV(M) = \text{Supp}(gr M)$

$M$  irreducible  $\leadsto AV(M)$  is finite union of  $K$ -orbits in  $\mathcal{N} \cup \mathfrak{p}$

• Take  $\mathcal{O} \subset \mathcal{N}$  nilpotent orbit,  $J$  unipotent ideal associated to  $\mathcal{O}$

•  $\text{codim}_{\mathbb{C}}(\partial \bar{\mathcal{O}} \cdot \bar{\mathcal{O}}) \geq 4$

[Losev & Yun, 23] classified irred  $M$  s.t.  $J \subset \text{Ann}(M)$  &  $AV(M) = \bar{\mathcal{O}}_K$   $\mathcal{O}_K$  is a  $K$ -orbit in  $\mathcal{O} \cup \mathfrak{p}$ .

•  $\text{codim}_{\mathbb{C}}(\partial \bar{\mathcal{O}} \cdot \bar{\mathcal{O}}) = 2$ , classification unknown!

Take  $\mathcal{O}' \subset \bar{\mathcal{O}}$  s.t.  $\text{codim}_{\mathbb{C}}(\mathcal{O}' \cdot \bar{\mathcal{O}}) = 2$

Take  $e' \in \mathcal{O}'$ ,  $e'$  a normal point in  $\bar{\mathcal{O}} \leadsto S'$ , Slodowy slice  $\leadsto S' \cap \bar{\mathcal{O}} \simeq X$ , a Kleinian singularity

$\mathcal{O} \curvearrowright S' \cap \bar{\mathcal{O}} \leadsto \underbrace{S' \cap \bar{\mathcal{O}} \cap \mathfrak{p}} = (S' \cap \bar{\mathcal{O}})^{\mathcal{O}} \simeq X^{\mathcal{O}}$ , fixed loci

$\mathcal{O} := -\sigma$ ,  $\mathfrak{p} := \mathfrak{g}^{\mathcal{O}}$   
anti-Poisson involution. local picture of  $AV(M)$  near  $e'$

## § 1. Reminder on Kleinian singularities

Let  $\Gamma \subset \mathrm{SL}_2(\mathbb{C})$  be a finite subgroup.

Kleinian singularity  $X := \mathbb{C}^2 / \Gamma = \mathrm{Spec} \mathbb{C}[u, v]^\Gamma$

Example:  $\Gamma = \{\pm I_2\}$  ( $A_1$ )

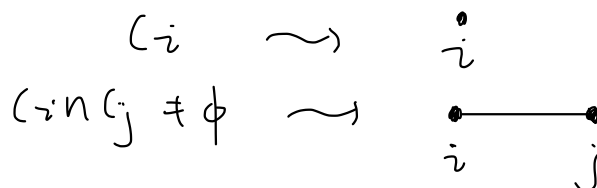

$$\begin{aligned} \mathbb{C}[u, v]^\Gamma &= \text{even degree polynomials} = \mathbb{C}[x = u^2, y = v^2, z = uv] \\ &= \mathbb{C}[x, y, z] / (xy - z^2) \end{aligned}$$

Theorem (Klein, 1884):  $X = \mathbb{C}^2 / \Gamma \hookrightarrow \mathbb{C}^3$  (single relation) /  
with an isolated singularity at 0.

$\pi: \tilde{X} \rightarrow X$ , minimal resolution

exceptional locus  $\pi^{-1}(0)_{\mathrm{red}} = \boxed{C_1} \cup \dots \cup C_n$   $C_i \cong \mathbb{P}^1$ .  
irreducible components

Dual graph of  $\pi^{-1}(0)_{\mathrm{red}}$ :

Fact (Du Val, 1934): Dual graphs of  $\pi^{-1}(0)_{\mathrm{red}}$  are ADE Dynkin diagrams.  
(bijection)

Rem:  $\pi^{-1}(0)$  is not reduced in general!

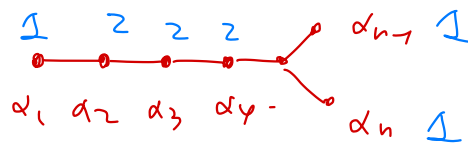

$\mathfrak{g}$ : simple Lie algebra of types ADE, simple root system  $\{\alpha_1, \alpha_2, \dots, \alpha_n\}$

$\delta$  - unique maximal root,  $\delta = \sum_{i=1}^n m_i \alpha_i$ . in the adjoint rep  $\mathfrak{g} \curvearrowright \mathfrak{g}$ .

Then we have  $\pi^{-1}(0) = \sum_{i=1}^n m_i C_i$  as a divisor. [Artin 66].

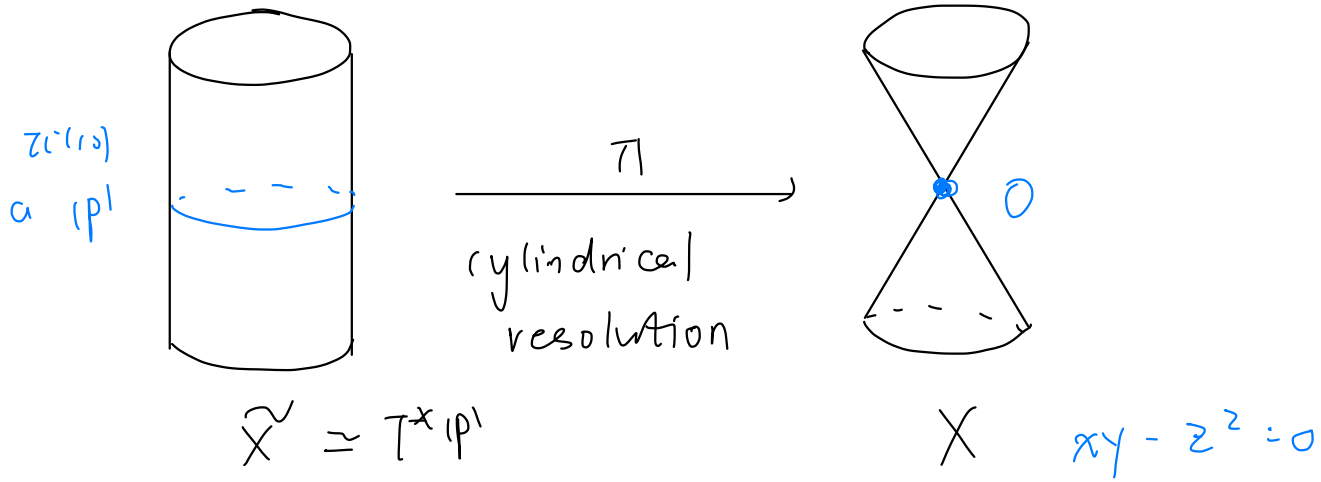

Type  $A_n$ :  $\alpha_i = \varepsilon_i - \varepsilon_{i+1}$ ,  $\delta = \varepsilon_1 - \varepsilon_{n+1} = \alpha_1 + \dots + \alpha_n \leadsto \pi^{-1}(0)$  reduced  
  $(m_1, \dots, m_n) = (1, \dots, 1)$

Type  $D_n$   $(m_1, \dots, m_n) = (1, 2, \dots, 2, 1, 1) \leadsto \pi^{-1}(0)$  not reduced

# Examples :

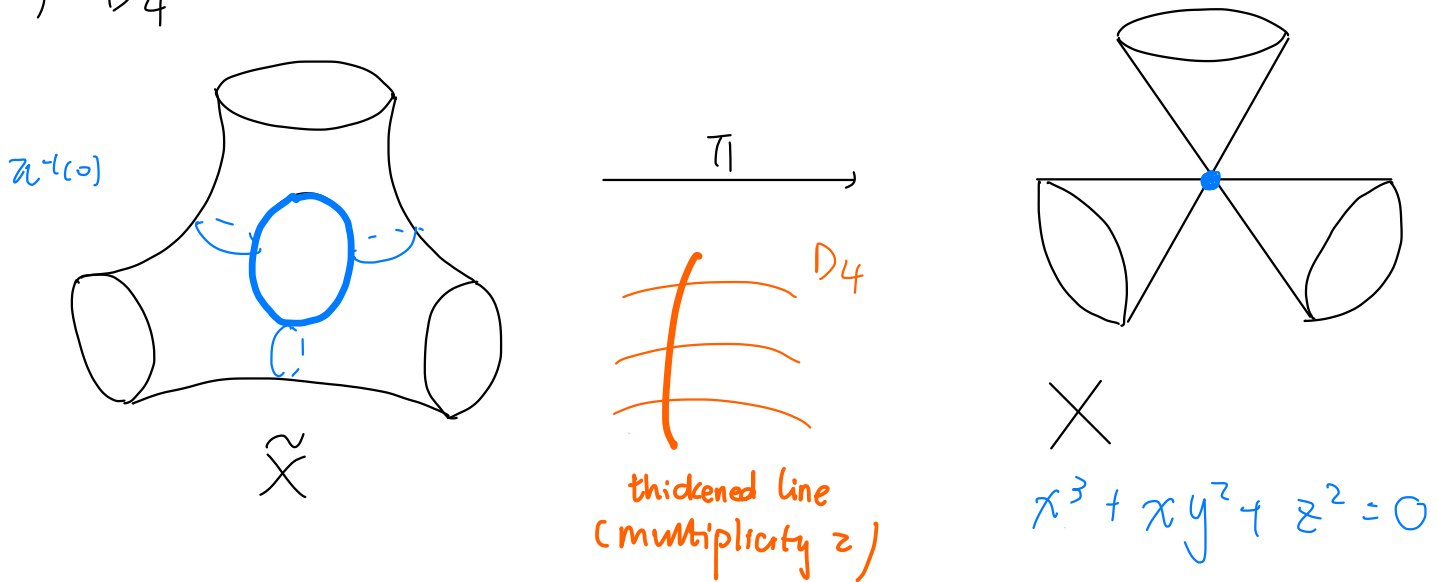

1)  $A_1$

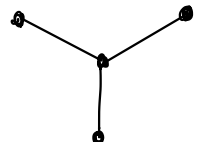

$\pi^{-1}(0)_{\text{red}} = \{p\}$  dual graph  $\bullet$   $A_1$  Dynkin diagrams

More generally, type A:  $\pi^{-1}(0)$   (reduced)

2)  $D_4$

dual graph   $D_4$  Dynkin diagram

## §2. Anti-Poisson involution

$$\mathbb{C}[u, v], \quad \text{Poisson bracket} \quad \{f_1, f_2\} = \frac{\partial f_1}{\partial u} \frac{\partial f_2}{\partial v} - \frac{\partial f_1}{\partial v} \frac{\partial f_2}{\partial u}$$

(deg = 2)

$\mathcal{P} \subset SL_2(\mathbb{C}) \leadsto \mathcal{P}$  preserves  $\{, \}$ .

$\leadsto \mathbb{C}[u, v]^{\mathcal{P}} \subset \mathbb{C}[u, v]$ , graded Poisson subalgebra (deg = 2)

Example: Type  $A_n$ :  $\mathbb{C}[X] = \mathbb{C}[x, y, z] / (xy - z^{n+1})$

$$\{x, y\} = (n+1)z^n$$

$$\{x, z\} = (n+1)x$$

$$\{y, z\} = -(n+1)y$$

Def: An anti-Poisson involution of a Kleinian singularity  $X \simeq \mathbb{C}^3/p$  is a graded algebra involution  $\theta: \mathbb{C}[X] \longrightarrow \mathbb{C}[X]$  such that

$$\theta(\{f_1, f_2\}) = -\{\theta(f_1), \theta(f_2)\} \quad \forall f_1, f_2 \in \mathbb{C}[X].$$

Example: Type  $A_n$ :  $\theta: \mathbb{C}[X] \longrightarrow \mathbb{C}[X]$

$$x \mapsto y, \quad y \mapsto x, \quad z \mapsto z$$

is an anti-Poisson involution.

Def (fixed locus):

$$X^{\theta} := \text{Spec } \mathbb{C}[X] / I, \quad \text{where } I = (\theta(f) - f, f \in \mathbb{C}[X])$$

Example (continued)

$$X^{\theta} = \text{Spec } \mathbb{C}[x, y, z] / (xy - z^{n+1}, x - y) \simeq \text{Spec } \mathbb{C}[x, z] / (x^2 - z^{n+1}) \text{ reduced.}$$

- union of two  $\mathbb{A}^1$  when  $n$  odd
- a cusp when  $n$  even.

## Prop 1 (Classification of $\theta$ )

There are finitely many anti-Poisson involutions on  $\mathbb{C}^2/T$  up to conjugation by Poisson automorphisms.

## Prop 2 (Description of $X^\theta$ )

(1)  $X^\theta_{\text{red}}$  is either a (singular) Lagrangian subvariety of  $X$ , or only contains the singular point.

(2)  $X^\theta$  is reduced and connected

Each irreducible component is either an  $\mathbb{A}^1$  or a cusp.

Proof (1) follows from

Lemma <sup>Exercise</sup>  $(M, \omega)$  symplectic manifold with anti-symplectic involution  $\tau$  ( $\tau^*\omega = -\omega$ )

$\hookrightarrow$  pf: look at tangent space

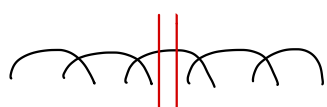

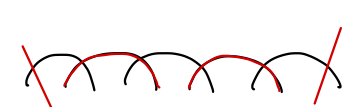

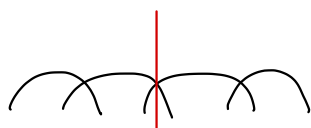

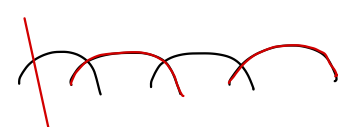

Then  $M^\tau$  is either empty or a Lagrangian submanifold.

applied to  $X^{\text{reg}} = X \setminus \{0\}$

(2) follows from classification in Prop 1 + case by case calculations.

# Example

Anti-Poisson involutions for Type  $A_n$  Kleinian singularity

	case I	case $\underline{II}$	case $\underline{III}$
$A_n, n \text{ odd}$ $xy - z^{n+1} = 0$ $X^0$ $\pi^{-1}(X^0)$	$x \leftrightarrow y$  	$z \mapsto -z$  	$x \mapsto -x$ $y \mapsto -y$  $z \mapsto -z$ 
$A_n, n \text{ even}$ $xy - z^{n+1} = 0$ $X^0$ $\pi^{-1}(X^0)$	$x \hookrightarrow y$   the only triple intersection	$x \mapsto -x$ $z \mapsto -z$  	Fixed loci in purple!

Corresponding Cartan  
involutions

outer involution  
 $\sigma: X \mapsto -X^T$

inner involution  
 $\sigma = \text{Ad}(I_{k,e})$

not seen.

$D_n, E_6$ , two cases of API ;  $E_7, E_8$  one case.

### §3 Preimage of fixed loci under minimal resolution

$$\pi: \tilde{X} \rightarrow X, \quad 0 \in X^\theta \mapsto \pi^{-1}(0) \subset \pi^{-1}(X^\theta)$$

§ 3.1 lift.

$$\theta: X \rightarrow X$$

Def: A lift of  $\theta: X \rightarrow X$  is an anti-symplectic involution  $\tilde{\theta}: \tilde{X} \rightarrow \tilde{X}$  s.t.  $\pi \circ \tilde{\theta} = \theta \circ \pi$

Thm 3: There exists a unique lift for any anti-Poisson involution  $\theta$  on  $X$ .

Now let's see why the lift helps to determine the preimage,  $\pi^{-1}(X^\theta)$

Claim:  $\pi^{-1}(X^\theta) = \underbrace{\pi^{-1}(0)}_{\text{union of } \mathbb{P}^1\text{'s}} \cup \boxed{\tilde{X}^{\tilde{\theta}}}$   $\tilde{X}^{\tilde{\theta}}$  is smooth Lagrangian (by Lemma)

no intersection!  $X$  becomes  $||$  in  $\pi^{-1}(X^\theta)$ ;

no cusp!  $\{$  becomes  $|$  in  $\pi^{-1}(X^\theta)$

Let  $L \subset X^\theta$  be an irreducible component

define  $\tilde{L} := \overline{\pi^{-1}(L \setminus 0)}$ , then  $\tilde{L}$  is an irreducible component in  $\pi^{-1}(X^\theta)$  &

$$\tilde{L} \subset \tilde{X}^{\tilde{\theta}} \Rightarrow \tilde{L} \text{ smooth.}$$

Claim  $\tilde{L} \simeq \mathbb{A}^1 \Rightarrow \tilde{L} \cap \pi^{-1}(0)$  is a single point in  $\pi^{-1}(0)^{\tilde{\theta}}$

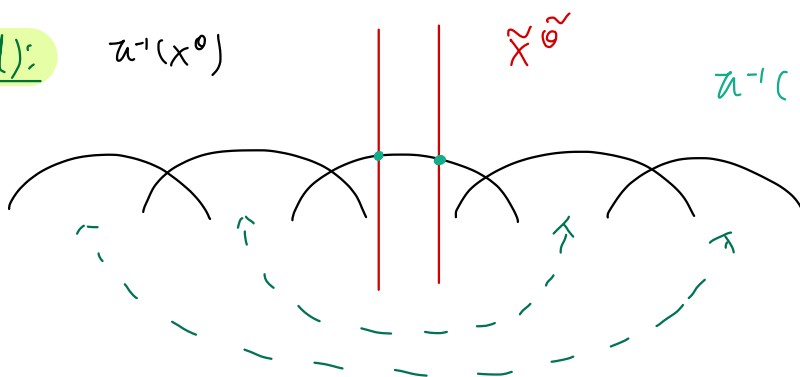

- The lift  $\tilde{\theta}$  sends  $\pi^{-1}(0)$  to  $\pi^{-1}(0)$  b/c ( $\theta(0)=0$ ),  
by permuting the components  $C_i \simeq \mathbb{P}^1$ . (swapping or preserve)

Lemma <sup>Exercise.</sup>: An involution on  $\mathbb{P}^1$  either acts trivially or has exactly two fixed points.

(comes from Möbius transformation)

Example (continued):

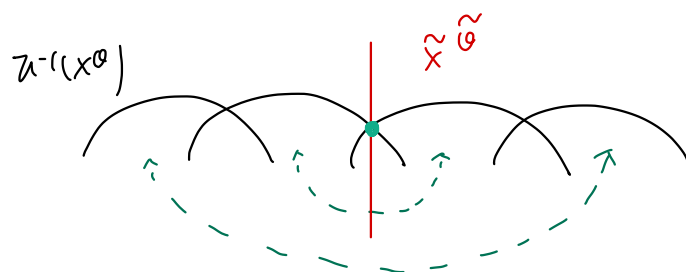

Type A:  $\theta: x \mapsto y$   
n odd

$\pi^{-1}(0)^{\tilde{\theta}} = \text{two discrete points}$

action of  $\tilde{\theta}$

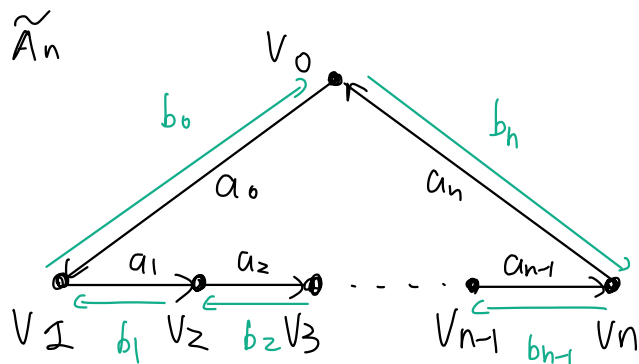

n even

$\pi^{-1}(0)^{\tilde{\theta}} = \text{a discrete point}$

### § 3-2 Nakajima quiver variety

Example: Nakajima quiver variety type A.

Attach to each vertex a 1-dim'l vector space  $V_i$

$\dim V_i = m_i$  ( $=1$  in type A)  
 $m_0 = 1$   $\rightarrow$  coefficient in  $\delta = \sum_{i=1}^n m_i \alpha_i$

Consider the representation space

$$M(\mathcal{V}) = \mathbb{A}^* \left( \bigoplus_{i=0}^n \text{Hom}(V_i, V_{i+1}) \right) = \bigoplus_{i=0}^n \text{Hom}(V_i, V_{i+1}) \oplus \bigoplus_{i=0}^n \text{Hom}(V_{i+1}, V_i)$$

symplectic vector space

$$G = \prod_{i=0}^n GL(V_i) \curvearrowright M(\mathcal{V}, \omega)$$

$$\text{moment map } \mu = (\mu_i)_{i=0}^n : \mu_i = a_i b_{i-1} - b_i a_i$$

$$\text{We have } \mu^{-1}(0) // G = \text{Spec } \mathbb{A}[\underbrace{\mu^{-1}(0)}_{\text{is also graded}}] // G \simeq \text{Spec } \mathbb{A}[x, y, z] / (xy - z^{n+1})$$

Type A<sub>n</sub> Kleinian singularity.

$$\text{with } x := a_n a_{n-1} \cdots a_1 a_0, \quad y := b_0 b_1 \cdots b_{n-1} b_n, \quad z := a_0 b_0 \quad \#$$

(product of determinant maps)

Take  $\chi: G \rightarrow \mathbb{C}^*$ , a generic character.

consider  $\mu^{-1}(0)^S \subset \mu^{-1}(0)$  (semi) stable locus.  $\sim G \curvearrowright \mu^{-1}(0)^S$  freely

Then  $\tilde{X} \simeq \mu^{-1}(0)^S // G \longrightarrow \mu^{-1}(0) // G \simeq X$

is the minimal resolution of Kleinian singularities [Kroheimer 89, Nakajima 94]

### Example (continued)

$$(1) \quad M(V) \longrightarrow M(V)$$

$$(2) \quad (a_i) = (b_{n+1-i}) \quad (1) \quad (b_i) = (a_{n+1-i}), \text{ anti-symplectic involution}$$

then (1) (1) preserves  $\mu^{-1}(0)$

routine check (2) (1) preserves  $\mu^{-1}(0)^S$

(3) (1) normalizes  $G$

$$(4) \quad (1)(x) = y, \quad (1)(y) = x, \quad (1)(z) = z \quad \leadsto (1) \text{ descends to } \Theta \text{ on } X.$$

$$\text{Thm (Nakajima 96)} \quad C_i = \{ (a, b) \in \mu^{-1}(0)^S // G \mid a_i = b_{i-1} = 0 \}$$

so  $\Theta(C_i) = C_{n+1-i}$  (swapping the components  $C_i, C_{n+1-i}$ )

corresponds to folding of Dynkin diagram  $A_n$ .

Rmk: types D, E can be done similarly; but main difficulty is that  $\dim V_i = m_i$ , not just 1-dim! making it hard to find invariant functions  $x, y, z$ .  
& no triple intersection in types D, E

### § 3.3 multiplicities

$X^\theta$  irreducible components  $L_1, \dots, L_m$   
reduced

$\pi^{-1}(X^\theta)$  irreducible components  $\underbrace{\tilde{L}_1, \dots, \tilde{L}_m}_{|A|}, \underbrace{C_1, \dots, C_n}_{|P|}$

$$\pi^{-1}(X^\theta) = \sum_{j=1}^m L_j + \sum_{i=1}^n \boxed{a_i} C_i \text{ as a divisor.}$$

↑  
want to determine  $a_i$

Define  $b_i := \#\{ \tilde{L}_j \mid \tilde{L}_j \cap C_i \neq \emptyset \}$

Prop 4 (multiplicity) If  $X^\theta \subset X$  is a principal divisor,

then 
$$\begin{pmatrix} a_1 \\ \vdots \\ a_n \end{pmatrix} = \boxed{C^{-1}} \begin{pmatrix} b_1 \\ \vdots \\ b_n \end{pmatrix}.$$

inverse of  
Cartan matrix

Rmk:  $X^\theta \subset X$  is principal modulo two cases  $\rightarrow$  have other method to determine multiplicity

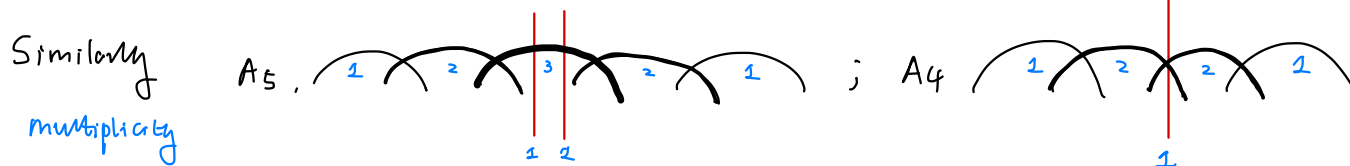

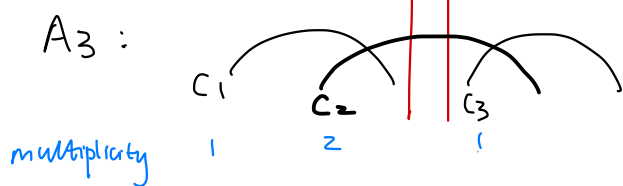

Example continued

Type  $A_n$ .  $\theta: X \hookrightarrow Y$  (case 1)

$$b_1 = 0, b_2 = 2, b_3 = 0$$

$$C \begin{pmatrix} a_1 \\ a_2 \\ a_3 \end{pmatrix} = \begin{pmatrix} b_1 \\ b_2 \\ b_3 \end{pmatrix} \leadsto \begin{pmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 2 \end{pmatrix} \begin{pmatrix} a_1 \\ a_2 \\ a_3 \end{pmatrix} = \begin{pmatrix} 0 \\ 2 \\ 0 \end{pmatrix}$$

$$\Rightarrow a_1 = 1, a_2 = 2, a_3 = 1$$

Not reduced unless for  $A_1$ .
